(54) Title: CLONING AND CHARACTERIZATION OF THE COMPLETE MAGE-1 GENE			
(57) Abstract			

The complete nucleotide and amino acid sequences of the human MAGE-1 antigen are provided. Peptides from residues of the C-terminal are used to define epitopes that stimulate HLA-restricted cytotoxic T lymphocyte activity against MAGE-1 antigens. The peptides are particularly useful in methods for stimulating the immune response of individuals against MAGE-1 antigens associated with melanomas.

5

CLONING AND CHARACTERIZATION OF THE COMPLETE MAGE 1 GENE

10

Background of the Invention

15

Tumor cells express certain antigens which are absent from, or present in small amounts on, their normal cellular counterparts. Most of these are differentiation antigens, shared by the tumor and various embryonic cells. Some of the antigens that appear with sufficient selectivity may serve as possible targets for therapeutic agents.

20

More than 40 different melanoma antigens have been defined with monoclonal antibodies, resulting in several major antigenic families with immunologically and biologically distinct characteristics. Among these families are: (1) the high molecular weight oncofetal proteins; (2) the gangliosides; (3) receptors for growth factors such as EGF, PDGF, TGF-alpha and TGF-beta, and nerve growth factor; (4) cation transport and binding proteins such as p97; (5) HLA class II antigens; (6) pigmentation-associated antigens; and (7) extracellular matrix proteins. Herlyn and Koproski, Ann. Rev. Immunol. 6: 283-308 (1988).

25

While preliminary studies with monoclonal antibody-based therapy and diagnosis directed toward various of these antigens are encouraging, work continues unabated in the hope that better agents and antigenic targets can be identified. Cutaneous malignant melanoma is increasing in prevalence at an alarming rate, particularly in the United States.

30

More recently a new family of antigens has been described on melanoma tumors. These antigens, now termed the "melanoma antigen," or MAGE family of antigens, were identified in a melanoma cell line which was lysed by a panel of autologous cytotoxic T lymphocytes ("CTLs"). Cells which did not express a MAGE-type antigen were not killed by the CTL, and by selecting these "antigen-loss" variants, six independent antigens were identified. Van den Eynde et al., Int. J. Cancer, 44: 634 (1989). A gene encoding one of the antigens, designated MZ2-E ("E"), has been cloned and

sequenced. Van der Bruggen et al., Science 254: 1643 (1991). The sequence was deposited in GenBank (accession #M77481), and comparison of the nucleotide sequence, designated "MAGE-1," failed to reveal any significant homology with any sequence in data banks, including GenBank. Two additional nonidentical cDNAs were also found (MAGE-2 and MAGE-3) which were more closely related to each other than to MAGE-1, but the three were approximately equally expressed.

10 Smaller regions of the MAGE-1 gene were cloned and transfected into cells. These transfectants expressed antigen which was recognized by the anti-E CTLs. Thus, it appears that the gene does not encode a protein which further activates an antigen-encoding gene. Van der Bruggen, id. The sequence encoding the antigenic peptide was speculated to be within the region of overlap of the segments. See Traversari et al., J. Exp. Med. 176: 1453-1457 (1992). The cDNAs of MAGE-2 and MAGE-3 were unable to transfer the expression of antigen E in transfection experiments. The presenting molecule for the E-antigen was thought to be HLA-A1.

20 The MAGE gene family has been shown by Van der Bruggen et al., id., to be expressed by a variety of different tumors and are not limited to melanomas, but they are not expressed by most normal cells. Thus, the MAGE antigens may have important implications for cancer immunotherapy. The sequence of the MAGE-1 gene was thought to be identical in 25 both normal tissues and in tumors.

What is needed in the art is a more thorough understanding of the immunogenic tumor-rejecting epitopes of the MAGE antigens. Once the immunodominant epitopes are identified, along with their HLA restriction, more effective therapeutic protocols can be devised. The present invention fulfills these and other related needs.

Summary of the Invention

35 This invention is based in part on the novel and unexpected observation that the previously reported gene encoding the human MAGE-1 protein encodes an additional fifty-eight amino acids at the C-terminal end. The complete human

MAGE-1 protein and peptides thereof can be produced by recombinant or synthetic means and may or may not have the biological activity of the native MAGE-1 antigen, depending on the intended use. Accordingly, isolated and purified 5 polynucleotides are described which code for the complete human MAGE-1 protein. The cDNA which codes for the full length human MAGE-1 protein may be incorporated into a recombinant DNA vector; which in turn may be used to transform a suitable host; the host cell transformed with the vector 10 including the cDNA can express full length human MAGE-1 protein, and the full length human MAGE-1 protein can be recovered.

This invention further concerns MAGE-1 immunogenic peptides from the C-terminus of the MAGE-1 protein which induce CTL activity. The immunogenic peptides of this 15 invention may be identified using motifs as described in copending U.S. patent applications S.N. 07/926,666 and S.N. 08/027,146 for the various MHC class I alleles. Thus, small synthetic or recombinant peptides can be prepared which 20 immunologically mimic MAGE-1 CTL inducing antigenic determinants. The CTL-inducing MAGE-1 peptides of the invention can be used therapeutically, for example, to induce, in the context of an appropriate MHC presenting molecule, an immunological response to tumors which express the 25 corresponding MAGE determinants. In this manner the tumor cells can be killed or inhibited. The induction of CTLs can be accomplished in vivo or ex vivo. Thus, the MAGE-1 peptides described herein also can be formulated and administered as 30 pharmaceutical compositions, especially when used to induce immunological responses in individuals predisposed to developing or already afflicted by a tumor which expresses MAGE-1 determinants.

In yet other embodiments the invention relates to methods for diagnosis, where the peptides of the invention are used to determine the presence in an individual of lymphocytes 35 which are capable of a cytotoxic T cell response to MAGE-1 antigen. Typically the lymphocytes are peripheral blood lymphocytes and the individual of interest is suffering from a

tumor associated with MAGE antigen. The diagnostic methods and compositions can be used in conjunction with therapeutic approaches to MAGE related diseases, and particularly the treatment of malignant melanoma.

5

Brief Description of the Drawings

Fig. 1 is the nucleotide and amino acid sequence of full length human MAGE-1 protein.

10

Fig. 2 is the nucleotide and amino acid sequence of the newly discovered C terminal portion of the full length human MAGE-1 protein.

15

Fig. 3 illustrates CTL responses specific for certain newly identified peptides from the C-terminus portion of the human MAGE-1 protein.

Description of the Specific Embodiments

20

The melanoma antigen termed "MAGE" was identified in the context of a CTL-inducing antigen. The MAGE antigen has since been discovered to be a family of related antigens expressed by a variety of tumor cells. The present invention provides the complete nucleotide sequence encoding human MAGE-1 antigen and the complete amino acid sequence thereof, thereby providing for the ultimate expression of the complete human MAGE-1 protein and new MAGE-1 peptides which have immunological activity. Recombinant DNA expression systems and chemical synthetic methods provide convenient means for obtaining large quantities of recombinant human MAGE-1 and the peptide fragments thereof in relatively pure form.

25

In preferred embodiments the peptides of the invention are derived from the region of the MAGE-1 antigen of the C-terminal 58 amino acids, as set forth in Seq. ID No. 1:

30 Seq. ID No. 1

35 Arg-Gln-Val-Pro-Asp-Ser-Asp-Pro-Ala-Arg-Tyr-Glu-Phe-Leu-Trp-Gly-Pro-Arg-Ala-Leu-Ala-Glu-Thr-Ser-Tyr-Val-Lys-Val-Leu-

Glu-Tyr-Val-Ile-Lys-Val-Ser-Ala-Arg-Val-Arg-Phe-Phe-Phe-Pro-Ser-Leu-Arg-Glu-Ala-Ala-Leu-Arg-Glu-Glu-Glu-Gly-Val

5 The peptide which is selected from the region of
Seq. ID No. 1 induces MHC HLA class I-restricted CTL responses
to MAGE expressing cells. The stimulated CTL, which secrete
lymphokines (e.g., gamma interferon) and liberate products
(e.g., proteolytic enzymes such as serine esterases) that
inhibit viral replication in infected autologous cells or
10 transfected cells, with or without cell killing, are able to
interrupt or substantially prevent the growth of MAGE
expressing tumor cells. In many instances the combination of
an effective cytotoxic T cell response and a protective
antibody response to selected tumor antigens will be preferred
15 for treating a MAGE-associated tumor.

In more preferred embodiments described herein an immunity-inducing peptide derived from the region of Seq. ID No. 1 has at least seven amino acids wherein a majority of amino acids of the peptide will be identical or substantially homologous, when compared to the amino acids comprising the corresponding portion of the naturally occurring MAGE-1 sequence. Representative peptides of this region are set forth in Table 1 below with MHC restriction indicated.

25 The peptide can be optionally flanked and/or modified at one or both of the N- and C-termini, as desired, by amino acids from MAGE sequences, particularly MAGE-1, amino acids added to facilitate linking, other N- and C-terminal modifications, linked to carriers, etc., as further described herein. The peptide induces a CTL response which is mediated 30 by at least the MHC class I molecule as indicated above.

The term "peptide" is used interchangeably with "oligopeptide" in the present specification to designate a series of residues, typically L-amino acids, connected one to the other typically by peptide bonds between the alpha-amino and carbonyl groups of adjacent amino acids. The oligopeptides of the invention are less than about 15 residues in length and usually consist of between about 8 and about 11 residues, preferably 9 or 10 residues.

By "immunogenic peptide" of the present invention is meant a peptide which comprises an allele-specific motif such that the peptide will bind the MHC allele and be capable of inducing a CTL response. The immunogenic peptides of this invention are derived from selected epitopic regions of the C-terminal 58 amino acid residues of the MAGE-1 antigen. The immunogenic peptides are capable of binding to an appropriate class I MHC molecule and inducing a cytotoxic T cell response against the MAGE antigen from which the immunogenic peptide is derived.

A "conserved residue" is an amino acid which occurs in a significantly higher frequency than would be expected by random distribution at a particular position in a peptide motif. Typically a conserved residue is one at which the immunogenic peptide may provide a contact point with the MHC molecule. One to three, preferably two, conserved residues within a peptide of defined length defines a motif for an immunogenic peptide. These residues are typically in close contact with the peptide binding groove, with their side chains buried in specific pockets of the groove itself. Typically, an immunogenic peptide will comprise up to three conserved residues, more usually two conserved residues.

As used herein, "negative binding residues" are amino acids which if present at certain positions will result in a peptide being a nonbinder or poor binder and in turn fail to induce a CTL response despite the presence of the appropriate conserved residues within the peptide.

The term "motif" refers to the pattern of residues in a peptide of defined length, usually about 8 to about 11 amino acids, which is recognized by a particular MHC allele. The peptide motifs are typically different for each human MHC allele and differ in the pattern of the highly conserved residues.

The binding motif for an allele can be defined with increasing degrees of precision. In one case, all of the conserved residues are present in the correct positions in a peptide and there are no negative binding residues present.

The phrases "isolated" or "biologically pure" refer to material which is substantially or essentially free from components which normally accompany it as found in its native state. Thus, the peptides of this invention do not contain materials normally associated with their in situ environment, e.g., MHC I molecules on antigen presenting cells. Even where a protein has been isolated to a homogenous or dominant band, there are trace contaminants in the range of 5-10% of native protein which co-purify with the desired protein. Isolated peptides of this invention do not contain such endogenous co-purified protein.

The term "residue" refers to an amino acid or amino acid mimetic incorporated in a oligopeptide by an amide bond or amide bond mimetic.

Peptides comprising the CTL epitopes are synthesized and the ability to bind appropriate MHC molecules is determined in assays using, for example, purified class I molecules and radioiodinated peptides and/or cells expressing empty class I molecules by, for instance, immunofluorescent staining and flow microfluorimetry, peptide-dependent class I assembly assays, and inhibition of CTL recognition by peptide competition. Those peptides that bind to the class I molecule are further chosen for their ability to serve as targets for CTLs derived from afflicted individuals, as well as for their capacity to induce primary in vitro or in vivo CTL responses that can give rise to CTL populations capable of reacting with tumor cells as therapeutic agents. Methods for determining allele-specific peptides and peptide motifs are described in co-pending commonly owned applications USSN 027,146 and USSN 027,746, which are incorporated herein by reference.

The peptides or oligopeptides can be prepared "synthetically," as described herein below, or by recombinant DNA technology. Although the peptide will preferably be substantially free of other naturally occurring human proteins and fragments thereof, in some embodiments the peptides can be conjugated to other MAGE fragments or other proteins or peptides which contribute directly or indirectly to an anti-tumor immunological response. The term peptide or

oligopeptide is used interchangeably with polypeptide in the present specification to designate a series of amino acids connected one to the other by peptide bonds between the alpha-amino and alpha-carboxy groups of adjacent amino acids.

5 The polypeptides or peptides can be a variety of lengths, either in their neutral (uncharged) forms or in forms which are salts, and either free of modifications such as glycosylation, side chain oxidation, or phosphorylation or containing these modifications, subject to the condition that
10 the modification not destroy the biological activity of the polypeptides as herein described.

Desirably, the peptide will be as small as possible while still maintaining substantially all of the biological activity of the large peptide. When possible, it may be
15 desirable to optimize peptides of the invention to a length of nine or ten amino acid residues, commensurate in size with processed peptides that are bound to MHC class I molecules on the cell surface. See generally, Schumacher et al., Nature 350:703-706 (1991); Van Bleek et al., Nature 348:213-216
20 (1990); Rotzschke et al., Nature 348:252-254 (1990); and Falk et al., Nature 351:290-296 (1991), which are incorporated herein by reference. By biological activity is meant the ability to bind an appropriate MHC molecule and, in the case of peptides useful for stimulating CTL responses, induce a CTL
25 response against MAGE antigen or antigen mimetic. In the case of a peptide analog antagonist, the analog will have biological activity if it competes with the peptide for binding to the MHC molecule and has a substantially reduced ability to stimulate a CTL response when compared to the native peptide. By a CTL response is meant a CD8⁺ T
30 lymphocyte response specific for the MAGE antigen of interest, e.g., members of the MAGE antigen family, wherein CD8⁺, MHC class I-restricted T lymphocytes are activated. As noted above, the activated T lymphocytes will secrete a variety of products which inhibit tumor cell replication and may or may not directly kill the tumor cell or other transfected cell
35 which expresses the appropriate MAGE antigenic determinant(s).

5 The terms "homologous", "substantially homologous", and "substantial homology" as used herein denote a sequence of amino acids having at least 50% identity wherein one sequence is compared to a reference sequence of amino acids. The percentage of sequence identity or homology is calculated by comparing one to another when aligned to corresponding portions of the reference sequence.

10 The peptides of the present invention or analogs thereof which have CTL stimulating activity may be modified to provide desired attributes other than improved serum half life. For instance, the ability of the peptides to induce CTL activity can be enhanced by linkage to a sequence which contains at least one epitope that is capable of inducing a T helper cell response. Particularly preferred immunogenic peptides/T helper conjugates are linked by a spacer molecule. The spacer is typically comprised of relatively small, neutral molecules, such as amino acids or amino acid mimetics, which are substantially uncharged under physiological conditions. The spacers are typically selected from, e.g., Ala, Gly, or other neutral spacers of nonpolar amino acids or neutral polar amino acids. It will be understood that the optionally present spacer need not be comprised of the same residues and thus may be a hetero- or homo-oligomer. When present, the spacer will usually be at least one or two residues, more usually three to six residues. Alternatively, the CTL peptide may be linked to the T helper peptide without a spacer.

15 20 25 30 35

The immunogenic peptide may be linked to the T helper peptide either directly or via a spacer either at the amino or carboxy terminus of the CTL peptide. The amino terminus of either the immunogenic peptide or the T helper peptide may be acylated.

In some embodiments it may be desirable to include in the pharmaceutical compositions of the invention at least one component which assists in priming CTL. Lipids have been identified as agents capable of assisting the priming CTL in vivo against certain antigens. For example, palmitic acid residues can be attached to the alpha and epsilon amino groups of a Lys residue and then linked, e.g., via one or more

linking residues such as Gly, Gly-Gly-, Ser, Ser-Ser, or the like, to an immunogenic peptide. The lipidated peptide can then be injected directly in a micellar form, incorporated into a liposome or emulsified in an adjuvant, e.g., incomplete Freund's adjuvant. In a preferred embodiment a particularly effective immunogen comprises palmitic acid attached to alpha and epsilon amino groups of Lys, which is attached via linkage, e.g., Ser-Ser, to the amino terminus of the immunogenic peptide.

As another example of lipid priming of CTL responses, *E. coli* lipoproteins, such as tripalmitoyl-S-glycerylcysteinylseryl-serine (P₃CSS) can be used to prime specific CTL when covalently attached to an appropriate peptide. See, e.g., Deres et al., Nature 342:561-564 (1989), incorporated herein by reference. Peptides of the invention can be coupled to P₃CSS, for example, and the lipopeptide administered to an individual to specifically prime a CTL response to the target antigen. Further, as the induction of neutralizing antibodies can also be primed with P₃CSS conjugated to a peptide which displays an appropriate epitope, the two compositions can be combined to more effectively elicit both humoral and cell-mediated responses to MAGE antigen.

As mentioned above, additional amino acids can be added to the termini of an oligopeptide or peptide to provide for ease of linking peptides one to another, for coupling to a carrier, support or larger peptide, for reasons discussed herein, for modifying the physical or chemical properties of the peptide or oligopeptide, or the like. Amino acids such as tyrosine, cysteine, lysine, glutamic or aspartic acid, or the like, can be introduced at the C- or N-terminus of the peptide or oligopeptide. In addition, the peptide or oligopeptide sequences can differ from the natural sequence by being modified by terminal-NH₂ acylation, e.g., by alkanoyl (C₁-C₂₀) or thioglycolyl acetylation, terminal-carboxy amidation, e.g., ammonia, methylamine, etc. In some instances these modifications may provide sites for linking to a support or other molecule.

It will be understood that the peptides of the present invention or analogs thereof which have CTL and/or T helper stimulating activity may be modified to provide other desired attributes, e.g., improved pharmacological characteristics, while increasing or at least retaining substantially all of the biological activity of the unmodified peptide. For instance, the peptides can be modified by extending, decreasing or substituting in the peptides amino acid sequences by, e.g., the addition or deletion of amino acids on either the amino terminal or carboxy terminal end, or both, of peptides derived from the sequences disclosed herein. The CTL activity of the subject peptides can be enhanced by linkage to a sequence which contains at least one epitope that is capable of inducing a T helper cell response, as explained above.

The peptides employed in the subject invention need not be identical to those exemplary peptides identified above or to a particular MAGE or MAGE-1 protein sequence, so long as the subject compounds are able to bind to the appropriate MHC molecule and provide for cytotoxic T lymphocytic or T helper activity against cells which express a MAGE antigen. Therefore, the peptides may be subject to various changes, such as insertions, deletions, and substitutions, either conservative or non-conservative, where such changes might provide for certain advantages in their use. By conservative substitutions is meant replacing an amino acid residue with another which is biologically and/or chemically similar, e.g., one hydrophobic residue for another, or one polar residue for another. The substitutions include combinations such as Gly, Ala; Val, Ile, Leu; Asp, Glu; Asn, Gln; Ser, Thr; Lys, Arg; and Phe, Tyr. Usually, the portion of the sequence which is intended to substantially mimic a MAGE CTL or T helper stimulating epitope will not differ by more than about 20% from the sequence of at least one member of the MAGE family, except where additional amino acids may be added at either terminus for the purpose of modifying the physical or chemical properties of the peptide for, e.g., ease of linking or coupling, and the like. In those situations where regions of

the peptide sequences are found to be polymorphic among MAGE antigens, it may be desirable to vary one or more particular amino acids to more effectively mimic differing cytotoxic T-lymphocyte or T helper epitopes of different MAGE antigens.

5 Using the methods described herein, two or more peptides may be identified which define different or overlapping CTL or T helper epitopes from a particular region. For example, using the methods described herein, two or more peptides may define different or overlapping CTL or T helper 10 epitopes from a particular region, e.g., the peptide region of the C-terminus of MAGE-1, or of a different region, which peptides can be combined in a "cocktail" to provide enhanced immunogenicity for CTL or T helper-mediated responses. Peptides of one region can also be combined with peptides 15 having different MHC restriction elements. This composition can be used to effectively broaden the immunological coverage provided by therapeutic, vaccine or diagnostic methods and compositions of the invention among a diverse population. When the peptides are linked, by covalent or non-covalent 20 means, it will be understood that linkage should not substantially interfere with either of the linked groups to function as described, e.g., to function as a MAGE cytotoxic T cell determinant or MAGE T helper determinant.

25 In another aspect the peptides of the invention can be combined or coupled with other peptides which present MAGE T helper cell epitopes, i.e., T helper peptides comprising six to thirty amino acids containing a T helper epitope from a MAGE protein or other immunogenic protein or derivative thereof to stimulate T cells that cooperate in the induction 30 of immune response against the MAGE antigen, e.g., in the CTL response to MAGE determinants. The T-helper cells can be either the T-helper 1 or T-helper 2 phenotype, for example. Compositions of T-helper peptides and CTL peptides thereby 35 enhance an individual's immunity by providing cell-mediated immunity and protective antibodies to MAGE antigen. T helper epitopes can be provided by peptides from, for example, tetanus toxoid 830-843 having the sequence Gln-Tyr-Ile-Lys-Ala-Asn-Ser-Lys-Phe-Ile-Gly-Ile-Thr-Glu (QYIKANSKFIGITE) [Seq. ID

No. 18]; malaria circumsporozoite 382-398 Lys-Ile-Ala-Lys-Met-Lys-Ala-Ser-Ser-Val-Phe-Asn-Val-Val-Asn-Ser (KIAKMEKASSVFNVVNS) [Seq. ID No. 19]; malaria circumsporozoite 378-398 Asp-Ile-Glu-Lys-Lys-Ile-Ala-Lys-Met-Lys-Ala-Ser-Ser-Val-Phe-Asn-Val-Val-Asn-Ser (DIEKKIAKMEKASSVFNVVNS) [Seq. ID No. 20]; ovalbumin 323-336 Ile-Ser-Gln-Ala-Val-His-Ala-Ala-His-Ala-Glu-Ile-Asn-Glu [Seq. ID No. 21], the influenza epitope 307-319 Pro-Lys-Tyr-Val-Lys-Gln-Asn-Thr-Leu-Lys-Leu-Ala-Thr [Seq. ID No. 22], and others.

In preferred embodiments the CTL inducing peptides of the invention are covalently linked to the T helper peptides. Particularly preferred CTL inducing peptides / T helper conjugates are linked by a spacer molecule.

Alternatively, the CTL peptide may be linked to the T helper peptide without a spacer. The T helper peptide is conjugated to the CTL peptide, preferably with the T helper peptide positioned at the amino terminus. The peptides may be joined by a neutral linker, such as Ala-Ala-Ala or the like, and preferably further contains a lipid residue such as palmitic acid or the like which is attached to alpha and epsilon amino groups of a Lys residue ((PAM)₂Lys), which is attached to the amino terminus of the peptide conjugate, typically via Ser-Ser linkage or the like.

The peptides of the invention can be prepared in a wide variety of ways. Because of their relatively short size, the peptides can be synthesized in solution or on a solid support in accordance with conventional techniques. Various automatic synthesizers are commercially available and can be used in accordance with known protocols. See, for example, Stewart and Young, Solid Phase Peptide Synthesis, 2d. ed., Pierce Chemical Co. (1984); Tam et al., J. Am. Chem. Soc. 105:6442 (1983); Merrifield, Science 232:341-347 (1986); and Barany and Merrifield, The Peptides, Gross and Meienhofer, eds., Academic Press, New York, pp. 1-284 (1979), each of which is incorporated herein by reference.

Alternatively, recombinant DNA technology may be employed wherein a nucleotide sequence which encodes a CTL peptide and/or T helper peptide of interest is inserted into

an expression vector, transformed or transfected into an appropriate host cell and cultivated under conditions suitable for expression. These procedures are generally known in the art, as described generally in Sambrook et al., Molecular Cloning, A Laboratory Manual, Cold Spring Harbor Press, Cold Spring Harbor, New York (1982), and Ausubel et al., (ed.) Current Protocols in Molecular Biology, John Wiley and Sons, Inc., New York (1987), and U.S. Pat. Nos. 4,237,224, 4,273,875, 4,431,739, 4,363,877 and 4,428,941, for example, 5 which disclosures are incorporated herein by reference. Thus, 10 fusion proteins which comprise one or more peptide sequences of the invention can be used to present the MAGE-1 CTL determinants. For example, a recombinant MAGE antigen 15 polypeptide is prepared in which the amino acid sequence is altered so as to more effectively present epitopes of peptide regions described herein to stimulate a CTL response.

As the coding sequence for peptides of the length contemplated herein can be synthesized by chemical techniques, for example, the phosphotriester method of Matteucci et al., 20 J. Am. Chem. Soc. 103:3185 (1981), modification can be made simply by substituting the appropriate base(s) for those encoding the native peptide sequence. The coding sequence can then be provided with appropriate linkers and ligated into 25 expression vectors commonly available in the art, and the vectors used to transform suitable hosts to produce the desired fusion protein. A number of such vectors and suitable host systems are now available. For expression, the coding sequence will be provided with operably linked start and stop codons, promoter and terminator regions and usually a 30 replication system to provide an expression vector for expression in the desired cellular host. Of course, bacterial, yeast or mammalian cell hosts may be used, employing suitable vectors and control sequences.

The complete MAGE-1 DNA sequence or fragments 35 encoding the C-terminal 58 amino acids of the MAGE-1 protein as described herein may be introduced into cultured mammalian cells by a variety of means, as will be recognized by those skilled in the art. For example, calcium phosphate- mediated

transfection (Wigler et al., Cell 14: 725, 1978; Corsaro and Pearson, Somatic Cell Genetics 7: 603, 1981; Graham and Van der Eb, Virology 52: 456, 1973), electroporation (Neumann et al., EMBO J. 1: 841-845, 1982), or DEAE-dextran mediated transfection (Ausubel et al., (ed.) Current Protocols in Molecular Biology, John Wiley and Sons, Inc., NY (1987), incorporated herein by reference) may find convenient use. To identify cells that have stably integrated the cloned DNA, a selectable marker is generally introduced into the cells along with the gene or cDNA of interest. Preferred selectable markers for use in cultured mammalian cells include genes that confer resistance to drugs, such as neomycin, hygromycin, and methotrexate. Further, the selectable marker may be an amplifiable selectable marker, and preferred amplifiable selectable markers include the DHFR gene and the neomycin resistance gene. Selectable markers are reviewed by Thilly (Mammalian Cell Technology, Butterworth Publishers, Stoneham, MA, which is incorporated herein by reference).

Transfected mammalian cells are allowed to grow for a period of time, typically 1-2 days, to begin expressing the MAGE-1 DNA sequence(s) of interest. Drug selection is then applied to select for growth of cells that are expressing the selectable marker in a stable fashion. For cells that have been transfected with an amplifiable selectable marker the drug concentration may be increased in a stepwise manner to select for increased copy number of the cloned sequences, thereby increasing expression levels.

Promoters, terminators and methods for introducing expression vectors encoding foreign proteins such as human MAGE-1 into plant, avian and insect cells are also well known in the art. Techniques for transforming fungi are well known in the literature, and have been described, for instance, by Beggs (Nature 275:104-108 (1978)), Hinnen et al. (Proc. Natl. Acad. Sci. USA 75: 1929-1933, 1978), Yelton et al. (Proc. Natl. Acad. Sci. USA 81: 1740-1747, 1984), Russell (Nature 301: 167-169, 1983) and U.S. Patent 4,935,349, incorporated herein by reference. Suitable yeast vectors for use in the present invention will generally include a selectable marker,

which may be one of any number of genes that exhibit a dominant phenotype for which a phenotypic assay exists to enable transformants to be selected.

5 Host cells containing DNA constructs which encode the complete MAGE-1 protein of the present invention or C-terminal fragments thereof are then cultured to produce the protein or peptides. The cells are cultured according to standard methods in a culture medium containing nutrients required for growth of the chosen host cells. A variety of 10 suitable media are known in the art. The growth medium will generally select for cells containing the DNA construct by, for example, drug selection or deficiency in an essential nutrient which is complemented by the selectable marker on the DNA construct or co-transfected with the DNA construct.

15 Selection of a medium appropriate for the particular cell line used is within the level of ordinary skill in the art. Cultured mammalian cells are generally cultured in commercially available serum-containing or serum-free media.

20 The complete MAGE-1 protein and C-terminal fragments thereof produced according to the present invention may be purified by, e.g., affinity chromatography on an antibody column using antibodies, preferably monoclonal antibodies, directed against corresponding MAGE epitopes. Additional purification may be achieved by conventional chemical 25 purification means, such as liquid chromatography, gradient centrifugation, and gel electrophoresis, among others. Methods of protein purification are known in the art (see generally, Scopes, R., Protein Purification, Springer-Verlag, NY (1982), which is incorporated herein by reference) and may 30 be applied to the purification of the recombinant human MAGE-1 described herein. Substantially pure recombinant human MAGE-1 of at least about 50% is preferred, at least about 70-80% more preferred, and 95-99% or more homogeneity most preferred, particularly for pharmaceutical uses. Once purified, 35 partially or to homogeneity, as desired, the recombinant human MAGE may then be used diagnostically, therapeutically, etc. as described herein.

The peptides of the present invention and pharmaceutical and vaccine compositions thereof are useful for administration to mammals, including humans, to treat and/or prevent tumors associated with expression of MAGE antigen.

5 For pharmaceutical compositions, the peptides, i.e., the CTL or T helper peptides or CTL/T helper peptide conjugates, as described above will be administered to an individual already suffering from a MAGE-associated tumor. Those in the early stages of tumor development can be treated
10 with the immunogenic peptides separately or in conjunction with other treatments, as appropriate. In therapeutic applications, compositions are administered to a patient in an amount sufficient to elicit an effective CTL response to a MAGE-bearing tumor and to cure or at least partially arrest
15 its symptoms and/or complications. An amount adequate to accomplish this is defined as "therapeutically effective dose." Amounts effective for this use will depend on, e.g., the peptide composition, the manner of administration, the stage and severity of the disease being treated, the weight
20 and general state of health of the patient, and the judgment of the prescribing physician, but generally range for the initial immunization (that is for therapeutic or prophylactic administration) from about 1.0 μ g to about 500 μ g of peptide for a 70 kg patient, followed by boosting dosages of from
25 about 1.0 μ g to about 100 μ g of peptide pursuant to a boosting regimen over weeks to months depending upon the patient's response and condition by measuring specific CTL activity in
the patient's blood. It must be kept in mind that the
peptides and compositions of the present invention may
30 generally be employed in serious disease states, that is, life-threatening or potentially life threatening situations. In such cases, in view of the minimization of extraneous substances and the relative nontoxic nature of the peptides, it is possible and may be felt desirable by the treating
35 physician to administer substantial excesses of these peptide compositions.

Single or multiple administrations of the compositions can be carried out with dose levels and pattern

being selected by the treating physician. In any event, the pharmaceutical formulations should provide a quantity of CTL or T helper stimulatory peptides of the invention sufficient to effectively treat the patient.

5 As individuals may develop MAGE-associated tumors because of an inadequate (or absent) CTL or T helper response during the earliest stages of tumor development, it is important to provide an amount of immuno-potentiating peptide in a formulation and mode of administration sufficient to effectively stimulate a CTL or T helper cell response.

10 Administration should continue until at least clinical symptoms or laboratory indicators indicate that the tumor has been eliminated or its progression has substantially abated and for a period thereafter. Immunizing doses followed by

15 boosting doses at established intervals, e.g., from one to four weeks, may be required, possibly for a prolonged period of time, as necessary to resolve the tumor.

20 The pharmaceutical compositions for therapeutic treatment are intended for parenteral, topical, oral or local administration. Preferably, the pharmaceutical compositions are administered parenterally, e.g., intravenously, subcutaneously, intradermally, or intramuscularly. Thus, the invention provides compositions for parenteral administration which comprise a solution of the CTL or T helper stimulatory peptides dissolved or suspended in an acceptable carrier, preferably an aqueous carrier. A variety of aqueous carriers may be used, e.g., water, buffered water, 0.4% saline, 0.3% glycine, hyaluronic acid and the like. These compositions may be sterilized by conventional, well known sterilization

25 techniques, or may be sterile filtered. The resulting aqueous solutions may be packaged for use as is, or lyophilized, the lyophilized preparation being combined with a sterile solution prior to administration. The compositions may contain pharmaceutically acceptable auxiliary substances as required

30 to approximate physiological conditions, such as pH adjusting and buffering agents, tonicity adjusting agents, wetting agents and the like, for example, sodium acetate, sodium

35

lactate, sodium chloride, potassium chloride, calcium chloride, sorbitan monolaurate, triethanolamine oleate, etc.

In some embodiments it may be desirable to include in the pharmaceutical composition at least one component which primes CTL. Certain lipids are capable of priming CTL responses in vivo, e.g., palmitic acid residues can be attached to the alpha and epsilon amino groups of a Lys residue and then linked to a synthetic peptide which comprises a class I-restricted CTL epitope. As further described herein, the lipidated peptide can then be incorporated into a liposome emulsified in an adjuvant, e.g., incomplete Freund's adjuvant. The arrangement of the components of the conjugate comprising the CTL inducing peptide/T helper peptide/lipid can be varied. In one case, the lipid moiety can be linked to the amino terminal end of the CTL inducing peptide, which in turn is linked at its carboxy terminal to the T helper peptide. In another case, the lipid is linked at the amino terminal end of the T helper peptide, which is linked at its carboxy terminal to the CTL inducing peptide. In each case, a spacer molecule, e.g., Lys-Ser-Ser, can be selectively inserted between the lipid moiety and the CTL or T helper peptide, as well as between the T helper and the CTL inducing peptides.

The concentration of CTL stimulatory peptides of the invention in the pharmaceutical formulations can vary widely, i.e., from less than about 1%, usually at or up to at least about 10%, to as much as 20 to 50% or more by weight, and will be selected primarily by fluid volumes, viscosities, etc., in accordance with the particular mode of administration selected. Thus, a typical pharmaceutical composition for intravenous infusion could be made up to contain 250 ml of sterile Ringer's solution, and 100 mg of peptide. Actual methods for preparing parenterally administrable compounds will be known or apparent to those skilled in the art and are described in more detail in for example, Remington's Pharmaceutical Sciences, 17th ed., Mack Publishing Company, Easton, PA (1985), which is incorporated herein by reference.

The peptides of the invention may also be administered via liposomes. Liposomes, which include

emulsions, foams, micelles, insoluble monolayers, phospholipid dispersions, lamellar layers and the like, can serve as a vehicle to target the peptides to a particular tissue, such as lymphoid tissue, or to tumor cells, as well as to increase the 5 half-life of the peptide composition. In these preparations the peptide to be delivered is incorporated as part of a liposome, alone or in conjunction with a molecule which binds to, e.g., a receptor prevalent among lymphoid cells or tumor cells, such as monoclonal antibodies, or with other 10 therapeutic or immunogenic compositions. A variety of methods are available for preparing liposomes, as described in, e.g., U.S. Patents 4,837,028 and 5,019,369, incorporated herein by reference.

In another aspect the present invention is directed 15 to vaccines which contain as an active ingredient an immunogenically effective amount of a CTL stimulating peptide as described herein. The peptide(s) may be introduced into a host, including humans, linked to its own carrier or as a homopolymer or heteropolymer of active peptide units. Such a 20 polymer has the advantage of increased immunological reaction and, where different peptides are used to make up the polymer, the additional ability to induce antibodies and/or cytotoxic T cells that react with different antigenic determinants of MAGE proteins. Useful carriers are well known in the art, and 25 include, e.g., thyroglobulin, albumins such as human serum albumin, tetanus toxoid, polyamino acids such as poly(D-lysine:D-glutamic acid), influenza, hepatitis B virus core protein, and the like. The vaccines can also contain a physiologically tolerable (acceptable) diluent such as water, 30 phosphate buffered saline, or saline, and further typically include an adjuvant. Adjuvants such as incomplete Freund's adjuvant, aluminum phosphate, aluminum hydroxide, or alum are materials well known in the art. Upon immunization with a peptide composition as described herein, via injection, 35 aerosol, oral, transdermal or other route, the immune system of the host responds to the vaccine by producing large amounts of CTLs specific for MAGE antigen, and the host becomes at

least partially immune to MAGE-bearing tumors or resistant to such tumors.

Vaccine compositions containing the peptides of the invention are administered to a patient susceptible to or otherwise at risk of developing MAGE-associated tumors, such as melanomas, to enhance the patient's own immune response capabilities. Such an amount is defined to be a "immunogenically effective dose." In this use, the precise amounts again depend on the patient's state of health and 10 weight, the mode of administration, the nature of the formulation, etc., but generally range from about 1.0 μ g to about 500 μ g per 70 kilogram patient, more commonly from about 50 μ g to about 100 μ g mg per 70 kg of body weight. CTL-inducing peptides are administered to individuals of an 15 appropriate HLA type. In some instances it may be desirable to combine the peptide vaccines of the invention with vaccines which induce neutralizing cellular or antibody responses to tumor antigens, such as the p97 tumor antigen, for example.

For therapeutic or immunization purposes, the 20 peptides of the invention can also be expressed by attenuated viral hosts, e.g., vaccinia or fowlpox. This approach involves the use of vaccinia virus as a vector to express nucleotide sequences that encode the peptides or conjugates of the invention. Upon introduction into a host, the recombinant 25 vaccinia virus expresses the MAGE peptide, and thereby elicits a host CTL or T helper response to MAGE antigen on the tumor cells. Vaccinia vectors and methods useful in immunization protocols are described in, e.g., U.S. Patent No. 4,722,848, incorporated herein by reference. A wide variety of other 30 vectors useful for therapeutic administration or immunization of the peptides of the invention will be apparent to those skilled in the art from the description herein.

The immunogenic peptides of the invention may be used to elicit CTL ex vivo. The resulting CTL can be used to 35 treat tumors in patients that do not respond to other conventional forms of therapy, or will not respond to a peptide vaccine approach of therapy. Ex vivo CTL responses to a MAGE expressing tumor are induced by incubating in tissue

culture a patient's CTL precursor cells (CTLp) together with a source of antigen-presenting cells (APC) and the appropriate immunogenic peptide. After an appropriate incubation time (typically 1-4 weeks), in which the CTLp are activated and 5 mature and expand into effector CTL, the cells are infused back into the patient, where they will inhibit or kill targeted tumor cells.

The peptides may also find use as diagnostic reagents. For example, a peptide of the invention may be used 10 to determine the susceptibility of a particular individual to a treatment regimen which employs the peptide or related peptides, and thus may be helpful in modifying an existing treatment protocol or in determining a prognosis for an affected individual. In addition, the peptides may also be 15 used to predict which individuals will be at substantial risk for developing MAGE-associated tumors.

The following examples are offered by way of illustration, not by way of limitation.

20

EXAMPLE 1
Cloning of Full Length MAGE DNA

The predicted coding region of MAGE-1 was cloned 25 from first strand cDNA synthesized from the MAGE-1 positive cell line 938 by PCR amplification using primers located at bp605-622 and bp1459-1476. The amplification was carried out using a high fidelity thermostable polymerase, Pfu, by cycling 30 times, 2 minutes at 95°C, 2 minutes at 50°C, and 2 minutes at 73°C. These conditions resulted in the amplification of a 30 870 bp fragment consistent with the predicted size for MAGE-1. The amplified fragment was subcloned in the vector pRc/RSV (Invitrogen) for further characterization.

The cloned fragment was sequenced using sequenase (v 35 2.0, USB) and MAGE-1 specific primers. Sequence characterization of the cloned fragment found a cytidine inserted at nucleotide 1377. This insertion falls immediately 3' of the sequence.

5 To determine if the insertion had been introduced during PCR amplification the genomic sequence of MAGE-1 from the original cell line as well as from four independent normal individuals was determined. Genomic DNA was isolated and the MAGE-1 gene was amplified using the same conditions used in the original cloning. The amplified fragment was cycle sequenced using an antisense primer corresponding to nucleotides 1427-1448. The procedures were as follows.

10 Genomic DNA Isolation: Cells from the MAGE-1 expressing cell line were taken directly from tissue culture stocks. The procedure for genomic DNA isolation from individuals was as follows: 15 mls of heparinized whole blood was mixed with 15 mls of RPMI 1640 media and layered over 20 mls of lymphocyte separation media and centrifuged for 15 15 minutes at 400 x g following the manufacturers protocol (Ficoll-Paque, Pharmacia). The cell layer was collected and washed twice in RPMI 1640 media. The lymphocytes were counted, resuspended at 4×10^6 cells/ml in 90% fetal bovine serum, 10% dimethyl sulfoxide and stored under liquid nitrogen 20 until further processing.

25 The thawed cell pellet was lysed in 400 μ l of lysis buffer (4.2 M guanidine thiocyanate, 25.5 mM sodium acetate, 122 mM β -mercaptoethanol). The lysate was extracted once with an equal volume of phenol/chloroform and then an equal volume of chloroform. Sodium acetate was added to a final concentration of 0.3 M and the DNA was precipitated with two volumes of ethanol. The purified genomic DNA was resuspended in 200 μ l of H₂O. The DNA concentration was determined by 30 fluorometry following the directions provided by the manufacturer (TKO 0100 Fluorometer, Hoeffer).

DNA Amplification

35 A 100 μ l reaction mix was prepared containing 0.5 μ g of genomic DNA, 0.5 μ M of each amplification primer (primers indicated above), 10 mM Tris-HCl (pH 8.8), 50 mM KCl, 1.5 mM MgCl₂, 0.001% (w/v) gelatin, all four deoxyribonucleotide triphosphates (dNTPs) each at 500 μ M, add 1.25 units of Taq DNA polymerase (Stratagene). The incubation conditions used

were: 30 cycles of 95°C, 2 minutes, 50°C, 2 minutes, 72°C, 2 minutes.

PCR DNA Fragment Purification:

5 The 100 μ l reaction mix was fractionated by electrophoresis through a 1% agarose (Seakem Agarose, FMC Inc.) gel, containing 10 μ g/ml ethidium bromide, 40 mM Tris-acetate, 1 mM EDTA. A gel slice containing the desired DNA fragment (870 bp for the MAGE-1 amplified fragment) was excised during UV illumination. The DNA was purified using a
10 glass bead purification kit (Qiaex, Qiagen) and was eluted in 20 μ l of H₂O.

DNA Sequencing:

15 All of the eluted DNA was sequenced with the appropriate primer (49 nucleotides downstream of the MAGE-1 amplified fragment) following the [³⁵S]dCTP incorporation protocol recommended by the manufacturers of the commercial cycle-sequencing kit (⁴Taq Cycle-Sequencing Kit, Untied States Biochemical). The sequencing reactions were fractionated by
20 electrophoresis through a 8% polyacrylamide gel (0.4 mm thick). The polyacrylamide gel was dried and exposed to X-ray film (XAR-5, Kodak) for 16 to 48 hours.

25 Each of the five MAGE 1 genes sequences contained the cytidine insertion at nucleotide 1377 when compared to the sequence in the GenBank entry. The insertion is significant because it shifts the reading frame of the gene, which changes
25 C-terminal amino acids and also extends the protein for an additional 33 amino acids. The full length DNA and amino acid sequence of human MAGE-1 protein is shown in Figure 1. Figure 2 shows the nucleotide and amino acid sequence of the newly
30 discovered C terminal portion to the human MAGE-1 protein.

EXAMPLE 2Identification of MAGE Immunogenic Peptides
from the C-Terminus

5 Using motifs for the various MHC class I alleles the C-terminus of the MAGE protein was analyzed for the presence of the motifs.

10 The motif for HLA-A3.2 comprises from the N-terminus to C-terminus a first conserved residue of L, M, I, V, S, A, T and F at position 2 and a second conserved residue of K, R or Y at the C-terminal end. Other first conserved residues are C, G or D and alternatively E. Other second conserved residues are H or F. The first and second conserved residues are preferably separated by 6 to 7 residues.

15 The motif for HLA-A1 comprises from the N-terminus to the C-terminus a first conserved residue of T, S or M, a second conserved residue of D or E, and a third conserved residue of Y. Other second conserved residues are A, S or T. The first and second conserved residues are adjacent and are preferably separated from the third conserved residue by 6 to 7 residues. A second motif consists of a first conserved residue of E or D and a second conserved residue of Y where the first and second conserved residues are separated by 5 to 6 residues.

20 The motif for HLA-A11 comprises from the N-terminus to the C-terminus a first conserved residue of T or V at position 2 and a C-terminal conserved residue of K. The first and second conserved residues are preferably separated by 6 or 7 residues.

25 The motif for HLA-A24.1 comprises from the N-terminus to the C-terminus a first conserved residue of Y, F or W at position 2 and a C terminal conserved residue of F, I, W, M or L. The first and second conserved residues are preferably separated by 6 to 7 residues.

30 The motif for HLA-A2.1 for 9 mer peptides includes one of the amino acids I, V, A and T at position 1 and V, L, I, A and M at position 9. Neither acidic amino acids nor P were found in position 1. Only one acidic amino acid and no

basic amino acids were found in position 3. Positions 6 and 7 showed no charged residues. Acidic amino acids, however, were frequently found in position 8, where they are tolerated, according to our definition of the A2.1 motif. The analysis 5 of the sequences of naturally processed peptides therefore reveals that >90% of the peptides followed the defined rules for a complete motif.

The motif for HLA-A2.1 for 10 mer peptides includes one of the amino acids L, M, I, V, A and T at position 2 and 10 V, I, L, A and M at position 10. In position 1 for example, in 10-mers again the P residue and acidic amino acids were not tolerated. In addition at position 1 in 10-mers aromatic residues were frequently observed in A2.1 binders. In position 3, acidic amino acids were frequently associated with 15 poor binding capacity in both 9-mers and 10-mers. Interestingly, however, while in position 3 aromatic residues were preferred in 9-mers, aliphatic residues (L, V, I, M) were preferred in 10-mers.

The immunogenic peptides of about 9 and 10 amino acids in length identified using the motifs are set forth in 20 Table 1.

5 Immunogenic peptides which were high and intermediate binders were then tested for their capacity to induce an *in vitro* CTL response.

10 The assay was carried out as follows:

15 To identify CTL epitopes, CTL was stimulated by SAC-I activated PBMCs as APC. Cold temperature expression of the MHC in which the β -2-microglobulin is unstable was utilized in addition to acid stripping to generate PBMC APC.

20 Complete Culture Medium. The tissue culture medium used in this study consisted of RPMI 1640 without Hepes (Biowhittaker) supplemented with 2 mM L-glutamine (Irvine Scientific), 0.5mM sodium pyruvate (Gibco), 100 U/100 μ g/ml penicillin/ streptomycin (Irvine), and 5% heat-inactivated Human Serum Type AB (RPMI/5% HS; Gemini Bioproducts). Culture media used in the growth of EBV-transformed lines contained 10% heat-inactivated fetal calf serum (RPMI/10% FCS, Irvine) instead of human serum.

25 Cytokines. Recombinant human interleukin-2 (rIL-2) and interleukin-4 (rIL-4) were obtained from Sandoz and used at a final concentration of 10 μ g/ml and 10 μ g/ml, respectively. Human interferon- γ (IFN- γ) and recombinant human Interleukin-7 (rIL-7) were obtained from Genzyme and used at 20 U/ml and 10 ng/ml, respectively.

30 Peptides. Peptides were synthesized on an automated synthesizer and are described in Table 1. Peptides were routinely diluted in 100% DMSO at 20 mg/ml, aliquoted, and stored at -70°C. Pools of peptides were tested with 2-3 peptides/pool with no more than 5 fold differences in Class I binding (if a pool was not possible for a specific peptide then individual peptides were tested).

35 Cell Lines. JY, Steinlin, EHM, BVR, and KT3 are homozygous human EBV-transformed B cell lines expressing HLA A_{2.1}, A₁, A₃, A₁₁, and A₂₄, respectively. They are grown in RPMI/10% FCS. K562, an NK cell sensitive, erythoblastoma line grown in RPMI/10% FCS, was used for reduction of background killing.

adjusted to the appropriate concentration for addition to the induction culture (see below).

5 c. Preparation of the CD4+ depleted PBMC responder cell population (depletion of lymphocyte sub-populations using AIS flasks). AIS MicroCollector T-150 flasks (specific for the depletion of CD4+ T cells; Menlo Park, CA) were primed by adding 25 ml of PBS/1 mM EDTA, swirling for 30 seconds so that all surfaces were moistened, and then 10 incubating with the binding surface down at room temperature for 1 hour. Following this incubation, flasks were shaken vigorously for 30 seconds, washed 1 time with PBS/EDTA, 2 additional times with PBS and then incubated with 25 ml of culture medium for 15 minutes. PBMCS were thawed in 15 serum-free RPMI (+ L-glutamine + Hepes) containing 30 μ g/ml DNase, washed once, and incubated for 15 minutes in culture medium. Following aspiration of culture medium from the flasks, up to 180 million PBMCS were added in 25 ml of culture medium containing 30 μ g/ml DNase. After 1 hour at room 20 temperature, the flasks were rocked gently for 10 seconds to resuspend the nonadherent cells. The nonadherent cell suspension containing the CD8+ T cells was collected and the flasks were washed 2 times with PBS. The CD4+ T cell depleted PBMCS were centrifuged and counted for addition to the 25 induction culture. The CD4+ and CD8+ phenotype of the CD4+ depleted cell population was determined by FACS analysis (see below). In general, this technique resulted in a two-fold enrichment for CD8+ T cells with an average of approximately 40-50% CD8+ T cells and 15-20% remaining CD4+ T cells 30 following depletion of CD4+ T cells.

35 d. Induction of primary CTL. During the 4 hour peptide loading of the stimulator APCs, CD4+ depleted PBMC to be used as the responder population were prepared utilizing AIS flasks for selection of CD8+ T cells through the depletion of CD4+ T cells (above). The responder cells were plated at 3×10^6 /ml in a 1 ml volume (24 well plate) and placed at 37°C until the peptide loaded stimulator APCs were prepared. The irradiated, peptide loaded APCs were washed 1 time in serum-free RPMI (+

L-glutamine and Hepes), adjusted to the appropriate concentration in complete medium, and plated into a 24 well plate at 1 ml/plate: For PBMC, 1×10^6 stimulator cells (1 ml volume) were plated into the wells containing the responder cells; For SAC-I activated PBMC and PHA blasts, 1 ml of 3×10^5 /ml stimulator cells were plated in each well. A final concentration of 10 $\mu\text{g}/\text{ml}$ of additional peptide was added in addition to 10 ng/ml final concentration of rIL-7 (2 ml total volume). The cells were cultured for 12 days. (For the "pulse only" induction protocol, the additional 10 $\mu\text{g}/\text{ml}$ of soluble peptide was not added to the cultures). On day 12, the cultures were restimulated with peptide pulsed adherent cells and tested for cytolytic activity 7 days later (below).

Protocol for Restimulation of Primary CTL Using Adherent APC. PBMCs were thawed into serum-free RPMI (+ L-glutamine and Hepes) containing 30 $\mu\text{g}/\text{ml}$ DNase, washed 2 times, and adjusted to 5×10^6 /ml in culture medium containing DNase. PBMCs (25 million cells/tube in 5 ml) were irradiated at 6100R. After 1 wash, the PBMCs were resuspended in culture medium and adjusted to 4×10^6 /ml. 1 ml of irradiated PBMCs was added per well of a 24-well plate. The PBMC were incubated for 2 hours at 37°C, washed 3 times to remove non-adherent cells, and cultured in medium containing 20 $\mu\text{g}/\text{ml}$ total peptide and 3 $\mu\text{g}/\text{ml}$ β_2 microglobulin added in a 0.5 ml volume and again incubated for 2 hours at 37°C. The peptide was aspirated and 1.5×10^6 responder cells resuspended in culture medium were added in a 1 ml volume. After 2 days, 1 ml of culture medium containing 20 U/ml rIL-2 was added.

FACS Analysis. One million cells/tube were centrifuged, resuspended in 100 $\mu\text{l}/\text{tube}$ PBS/0.1% BSA/0.02% sodium azide (Sigma) plus 10 $\mu\text{l}/\text{tube}$ directly conjugated antibody (Becton Dickinson), and incubated on ice 15-20 minutes. Cells were then washed 2 times with PBS/0.1% BSA/0.02% sodium azide and resuspended in PBS to analyze on FACScan (Becton Dickinson). When it was not possible to analyze samples within 1-2 days, cells were fixed with PBS

containing 1% paraformaldehyde (Fisher) and analyzed within one week.

Cytotoxicity Assays

5 a. Target cell preparation. Approximately 16-20 hours prior to the CTL assay, target cells (Class I matched EBV-transformed lines) were washed once and resuspended in a 10 ml volume at 3×10^5 /ml in RPMI/5% FCS in the presence or absence of 10 μ g/ml total peptide.

10 b. Labeling of target cells: Target cells were centrifuged and resuspended in 200 μ l/tube sodium ^{51}Cr chromate (NEN), then incubated at 37°C for 1 hour on a shaker. Targets were washed 3 times (10 ml/wash) with RPMI/10% FCS and resuspended in 10 ml (to determine the efficiency of labelling, 50 μ l/target was counted on the Micromedic 15 automatic gamma counter).

20 c. CTL assay. Target cells were adjusted to 2×10^5 /ml and 50 μ l of the cell culture was added to each well of a U-bottomed 96-well plate (Costar Corp.) for a final concentration of 1×10^4 /well. K562 cells were washed once, resuspended at 4×10^6 /ml, and 50 μ l/well was added for a final concentration of 2×10^5 /well (ratio of cold K562 to target was 20:1). Responder cells were washed once, resuspended at 9×10^6 /ml, and three fold serial dilutions were performed for effector to target ratios of 90:1, 30:1, 25 10:1, and 3:1. Responder cells were added in a volume of 100 μ l in duplicate wells. For spontaneous release, 50 μ l/well of labelled target cells, 50 μ l/well K562, and 100 μ l/well of medium was added. For maximum release, 50 μ l/well target, 50 μ l/well K562, and 100 μ l/well of 0.1% Triton-X100 (Sigma) was 30 added. Plates were centrifuged for 5 minutes at 1200 RPM. Following a 5 hour incubation at 37°C, plates were centrifuged again for 5 minutes at 1200 RPM, and 100 μ l/well of supernatant was collected. Standard gamma counting techniques (Micromedic automatic gamma counter; 0.5 minutes/tube) were 35 used to determine the percent specific lysis according to the formula: % specific lysis = cpm experimental - cpm spontaneous release/cpm maximum release - cpm spontaneous release X 100. A CTL assay was considered positive if the lysis by CTL of

5

targets sensitized with a specific peptide at the two highest effector to target (E:T) ratios was 15% greater than lysis of control targets (i.e., target cells without peptide). A cytotoxicity assay was considered borderline if the lysis by CTL of targets sensitized with a specific peptide at the two highest E:T ratios was 6% greater than lysis of control targets. Of the 63 MAGE peptides that bind to the indicated alleles 12 induced primary CTL responses.

10

Results of the CTL assays are shown in Fig. 3.

Although the present invention has been described in some detail by way of illustration and example for purposes of clarity and understanding, it will be apparent that certain changes and modifications may be practiced within the scope of the appended claims.

SEQUENCE LISTING

(1) GENERAL INFORMATION:

(i) APPLICANT:

- (A) NAME: Cytel Corporation
- (B) STREET: 3525 John Hopkins Court
- (C) CITY: San Diego
- (D) STATE: California
- (E) COUNTRY: United States of America
- (F) POSTAL CODE (ZIP): 92121

What is claimed:

5 1. An immunogenic peptide comprising about nine to
ten amino acids, wherein said peptide is from the C terminal
58 amino acids of Sequence ID. No. 1.

10 2. The immunogenic peptide of claim 1 having an
HLA-A 1/11 binding motif wherein the immunogenic peptide is
selected from the group consisting of:

274 MAGE1N Glu-Thr-Ser-Tyr-Val-Lys-Val-Leu-Glu-Tyr,
(A01/11) [Seq. ID No. 2]; and
275 MAGE1N Thr-Ser-Tyr-Val-Lys-Val-Leu-Glu-Tyr,
(A01/11) [Seq. ID No. 3];

15 3. The immunogenic peptide of claim 1 having an
HLA-A2 binding motif wherein the immunogenic peptide is
selected from the group consisting of:

279 MAGE1N Lys-Val-Leu-Glu-Tyr-Val-Ile-Lys-Val,
20 (A02) [Seq. ID No. 4];
265 MAGE1N Phe-Leu-Trp-Gly-Pro-Arg-Ala-Leu-Ala,
 (A02) [Seq. ID No. 5];
302 MAGE1N Ala-Leu-Arg-Glu-Glu-Glu-Gly-Val,
 A02 [Seq. ID No. 6];
25 271 MAGE1N Ala-Leu-Ala-Glu-Thr-Ser-Tyr-Val-Lys-Val,
 A02 [Seq. ID No. 7];
283 MAGE1N Tyr-Val-Ile-Lys-Val-Ser-Ala-Arg-Val,
 (A02) [Seq. ID No. 8]; and
270 MAGE1N Arg-Ala-Leu-Ala-Glu-Thr-Ser-Tyr-Val,
30 (A02) [Seq. ID No. 9];

4. The immunogenic peptide of claim 1 having an HLA
A3/A11 binding motif wherein the immunogenic peptide is
selected from the group consisting of:

35 275 MAGE1N Thr-Ser-Tyr-Val-Lys-Val-Leu-Glu-Tyr,
 (AA03/11) [Seq. ID No. 10];
290 MAGE1N Arg-Val-Arg-Phe-Phe-Phe-Pro-Ser-Leu-Arg,
 (A03/11) [Seq. ID No. 11];

271 MAGE1N Ala-Leu-Ala-Glu-Thr-Ser-Tyr-Val-Lys-Val-Lys,
A03/11 [Seq. ID No. 12];
270 MAGE1N Arg-Ala-Leu-Ala-Glu-Thr-Ser-Tyr-Val-Lys,
(A03/11) [Seq. ID No. 13];
5 242 MAGE1N Asp-Leu-Val-Gln-Glu-Lys-Tyr-Leu-Glu-Tyr,
(A03) [Seq. ID No. 14];
283 MAGE1N Tyr-Val-Ile-Lys-Val-Ser-Ala-Arg-Val-Arg,
(A03) [Seq. ID No. 15]; or
243 MAGE1N Leu-Val-Gln-Glu-Lys-Tyr-Leu-Glu-Tyr,
10 (A11) [Seq. ID No. 16];

5. The immunogenic peptide of claim 1 having an HLA-A24 binding motif wherein the immunogenic peptide is:

276 MAGE1N Ser-Tyr-Val-Lys-Val-Leu-Glu-Tyr-Val-Ile,
15 (A24) [Seq. ID No. 17].

6. An isolated DNA encoding an immunogenic peptide selected from the C terminal 58 amino acids of Sequence I.D. No. 1.

20 7. A vector comprising DNA encoding an immunogenic peptide selected from the C terminal 58 amino acids of Sequence I.D. No. 1.

25 8. A host cell transformed with the vector of claim 6.

SUBSTITUTE SHEET (RULE 26)

INTERNATIONAL SEARCH REPORT

International application No.
PCT/US94/08721

A. CLASSIFICATION OF SUBJECT MATTER

IPC(6) :Please See Extra Sheet.

US CL :Please See Extra Sheet.

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

U.S. : 424/277.1; 435/69.3, 240.2, 252.3, 254, 320.1; 530/324, 327, 328, 828; 935/12

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)

Please See Extra Sheet.

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
X	SCIENCE, Volume 254, issued 13 December 1991, P. Van Der Bruggen et al., "A Gene Encoding an Antigen Recognized by Cytolytic T Lymphocytes on a Human Melanoma", pages 1643-1647, see entire document.	1-8
X	INTERNATIONAL JOURNAL OF CANCER, Volume 52, issued 1992, F. Brasseur et al., "Human Gene MAGE-1, Which Codes for a Tumor Rejection-Antigen, is Expressed by Some Breast Tumors", pages 839-841, see entire document.	1-8

 Further documents are listed in the continuation of Box C. See patent family annex.

Special categories of cited documents:	
"A"	document defining the general state of the art which is not considered to be of particular relevance
"E"	earlier document published on or after the international filing date
"L"	document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
"O"	document referring to an oral disclosure, use, exhibition or other means
"P"	document published prior to the international filing date but later than the priority date claimed
"T"	later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
"X"	document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
"Y"	document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art
"Z"	document member of the same patent family

Date of the actual completion of the international search

05 OCTOBER 1994

Date of mailing of the international search report

25 NOV 1994 -

Name and mailing address of the ISA/US
Commissioner of Patents and Trademarks
Box PCT
Washington, D.C. 20231

Facsimile No. (703) 305-3230

Authorized officer

ANTHONY C. CAPUTA, Ph.D.

Telephone No. (703) 308-0196

INTERNATIONAL SEARCH REPORT

International application No.

PCT/US94/08721

A. CLASSIFICATION OF SUBJECT MATTER:

IPC (6):

A61K 38/00, 39/00; C07H 21/04; C12N 1/19, 1/21, 5/10, 15/00, 15/70, 15/79; C12P 21/06

A. CLASSIFICATION OF SUBJECT MATTER:

US CL :

424/277.1; 435/69.3, 240.2, 252.3, 254, 320.1; 530/324, 327, 328, 828; 935/12

B. FIELDS SEARCHED

Electronic data bases consulted (Name of data base and where practicable terms used):

APS, CA, BIOSIS, MEDLINE, EMBASE, WPIDS,
search terms: fikes, j?, livingston, b?, sette, a?, mage 1, mage, terminal, end, carboxyl, C terminal,
